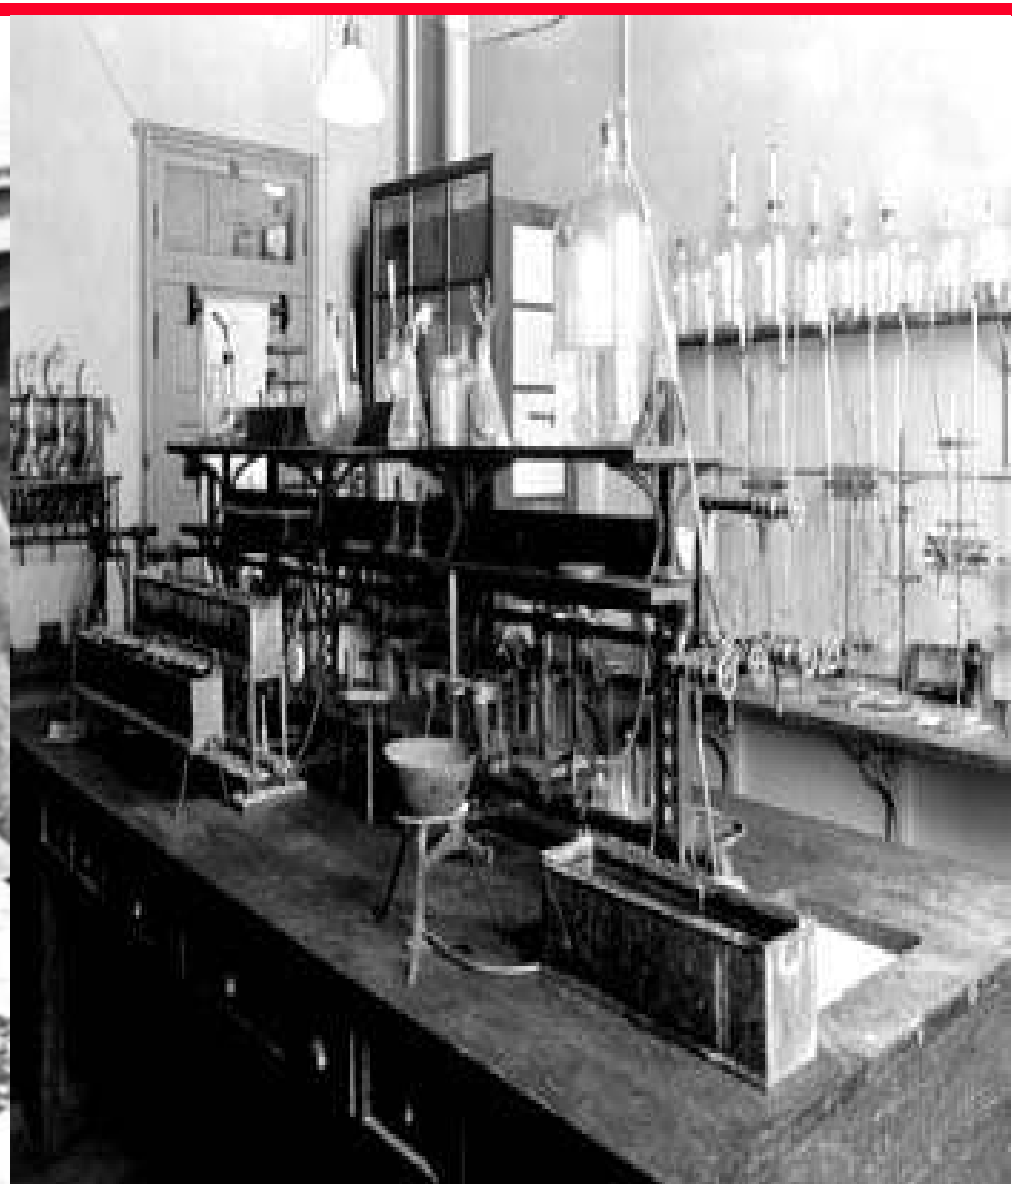
Banting & Best



One of the first diabetic patients to be treated with insulin extracted

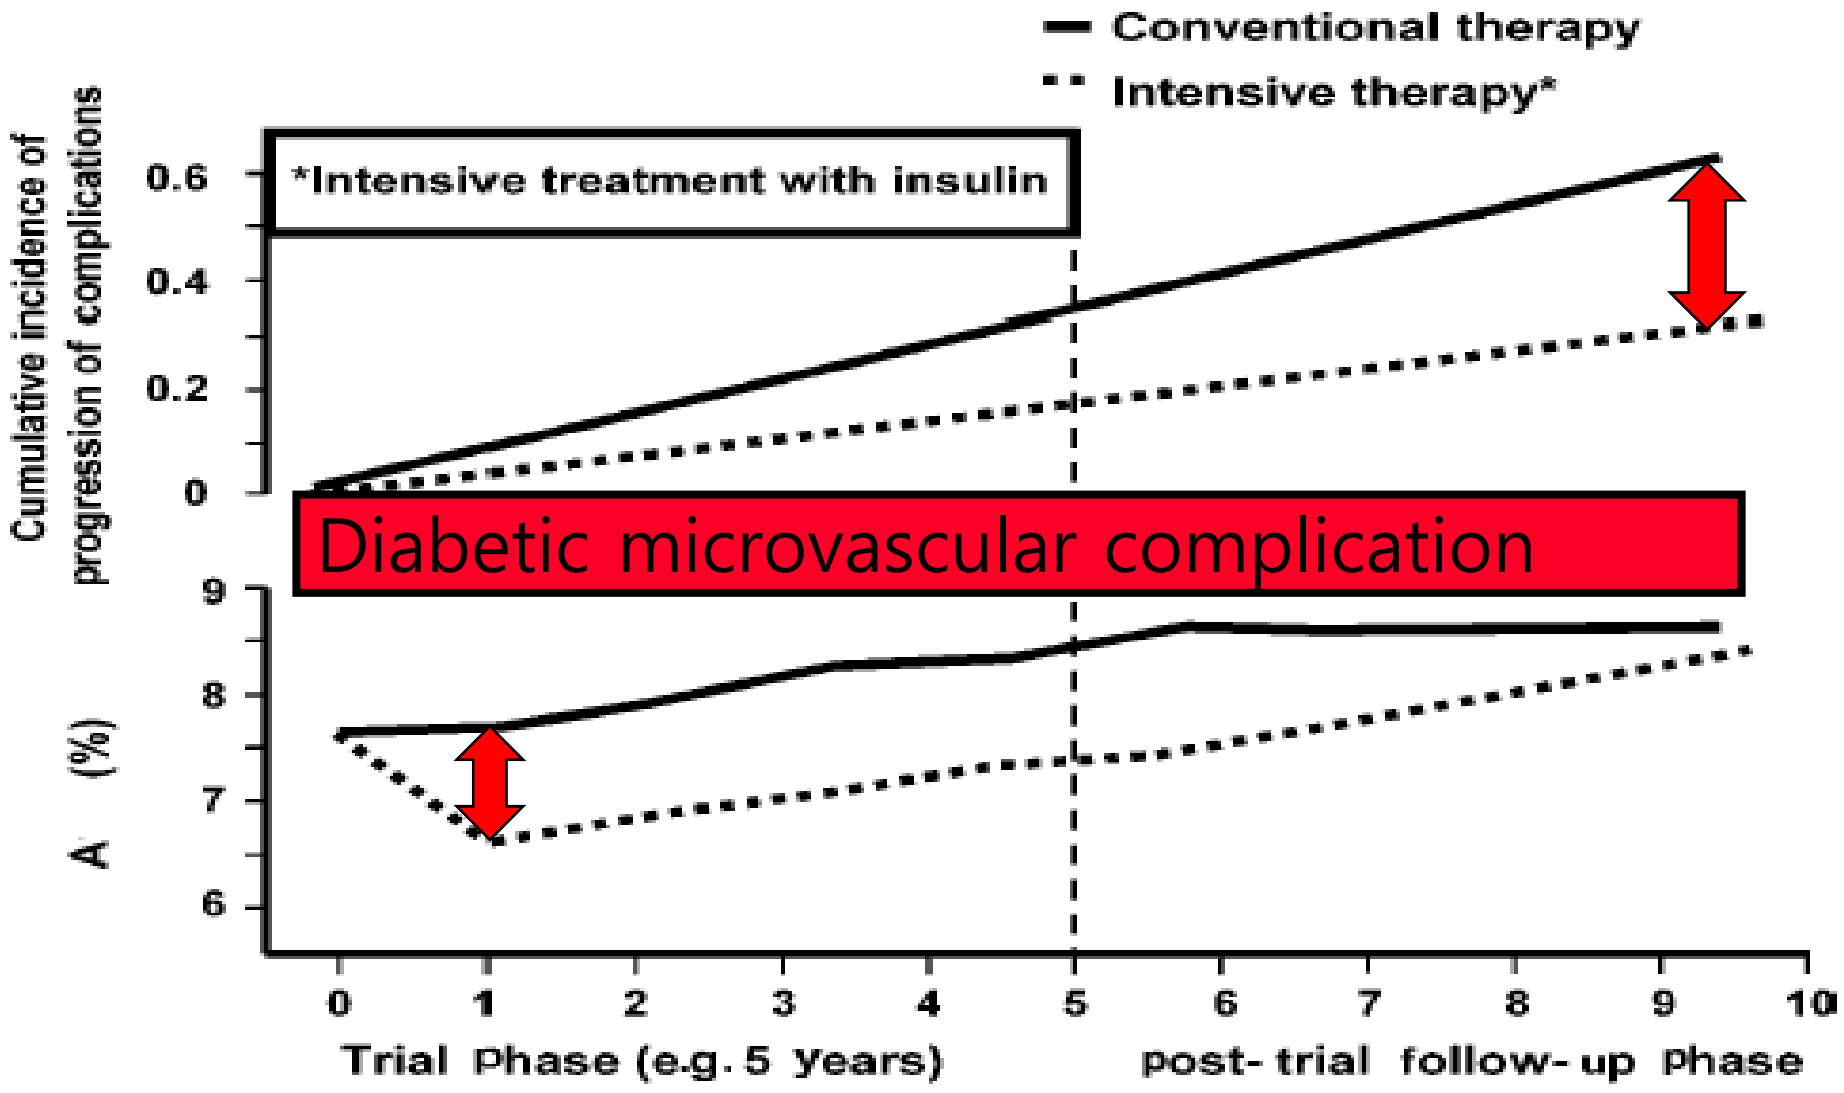
- 13세 어린 소녀
- 체중은 불과 45lbs(20.4 kg)
- Her chances of surviving for much longer are very, very poor(1921).
- 도축한 소 췌장에서 추출한 인슐린 사용

절박함에서 나온 용기

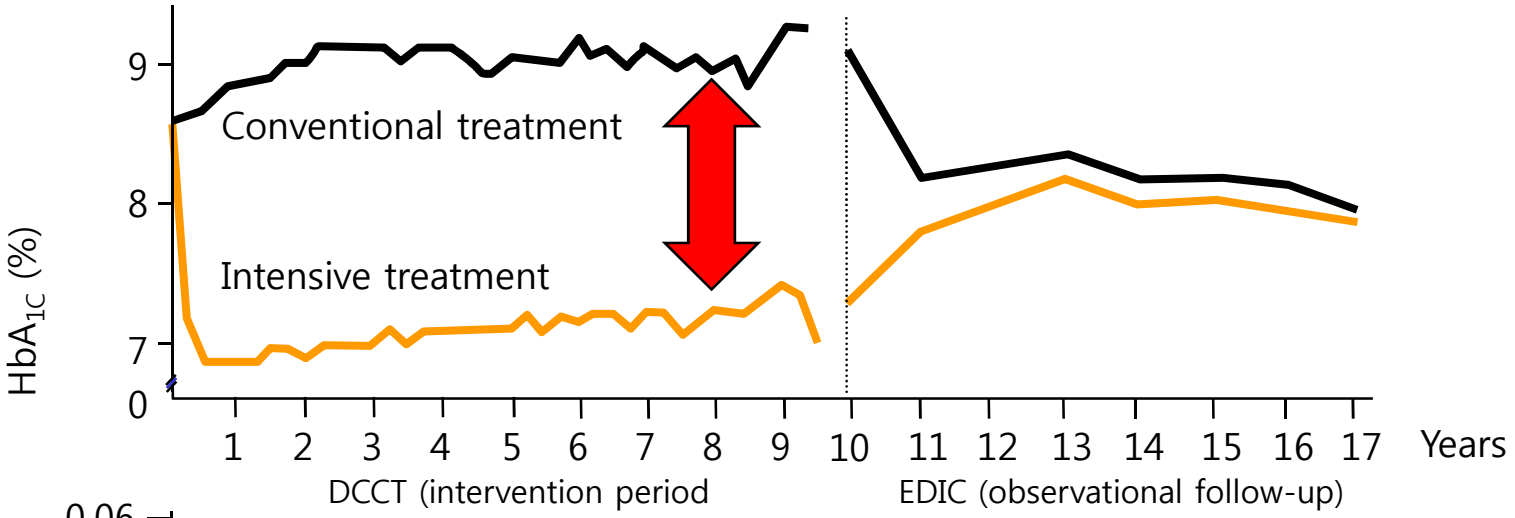
- I would have died from type 1 diabetes when I was 8 years old. However, it was already apparent at the time I was diagnosed that for too many people like me, Banting's discovery of insulin only allowed them to live just long enough to develop blindness, renal failure, and coronary disease.

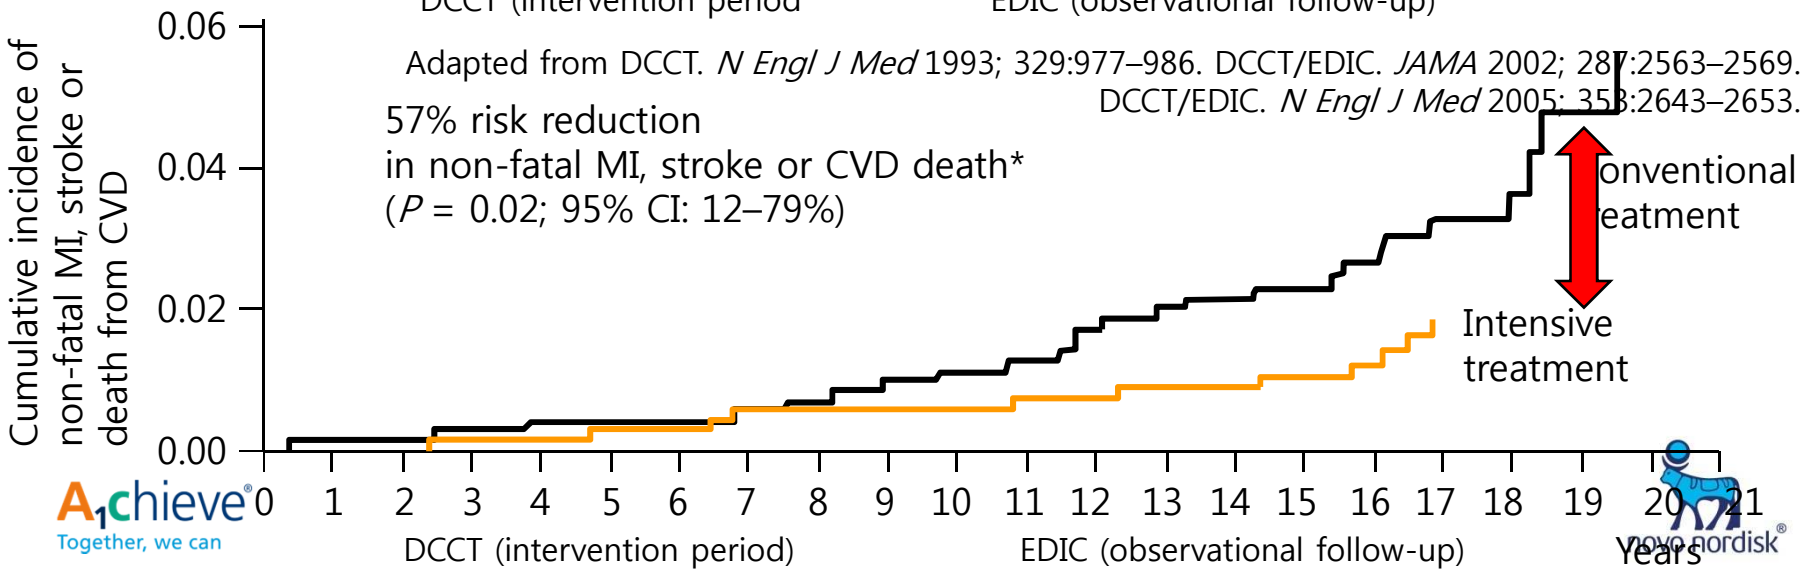
Brownlee M. 2004 ADA Baning Lecture

Initial metabolic control changes biology of diabetes



DCCT/EDIC: glycemic control reduces the risk of non-fatal MI, stroke or death from CVD in type 1 diabetes





*Intensive vs conventional treatment

10-Year Follow-up of Intensive Glucose Control in Type 2 Diabetes

Rury R. Holman, F.R.C.P., Sanjoy K. Paul, Ph.D., M. Angelyn Bethel, M.D., David R. Matthews, F.R.C.P., and H. Andrew W. Neil, F.R.C.P.

❖20-year Interventional Trial from 1977 to 1997

- 5,102 patients with newly-diagnosed type 2 diabetes recruited between 1977 and 1991
- Median follow-up 10.0 years, range 6 to 20 years

❖ 10-year Post-Trial Monitoring from 1997 to 2007

- Annual follow-up of the survivor cohort
- Clinic-based for first five years
- Questionnaire-based for last five years

- ***Median overall follow-up 17.0 years, range 16 to 30 years***

Wholistic approach in diabetic treatment
- Steno 2 study -

VBWG

Steno-2 supports aggressive multifactorial intervention in type 2 diabetes

- Target-driven, long-term, intensified intervention aimed at multiple risk factors in patients with type 2 diabetes and microalbuminuria
  - Blood pressure <130/80 mm Hg
  - A_{1c} <6.5%
  - Total cholesterol <175 mg/dL
  - Triglycerides <150 mg/dL
- Produced risk reductions in CV and microvascular outcomes
  - Primary outcome (combined CV disease) 53%↓
  - Nephropathy 61%↓
  - Retinopathy 58%↓
  - Autonomic neuropathy 63%↓

ORIGINAL ARTICLE

Three-Year Efficacy of Complex Insulin Regimens in Type 2 Diabetes

Rury R. Holman, M.B., Ch.B., F.R.C.P., Andrew J. Farmer, D.M., F.R.C.G.P., Melanie J. Davies, M.D., F.R.C.P., Jonathan C. Levy, M.D., F.R.C.P., Julie L. Darbyshire, M.A., M.Sc., Joanne F. Keenan, B.A., and Sanjoy K. Paul, Ph.D., for the 4-T Study Group*

Treating to Target in Type 2 diabetes (4T) Study

Rationale

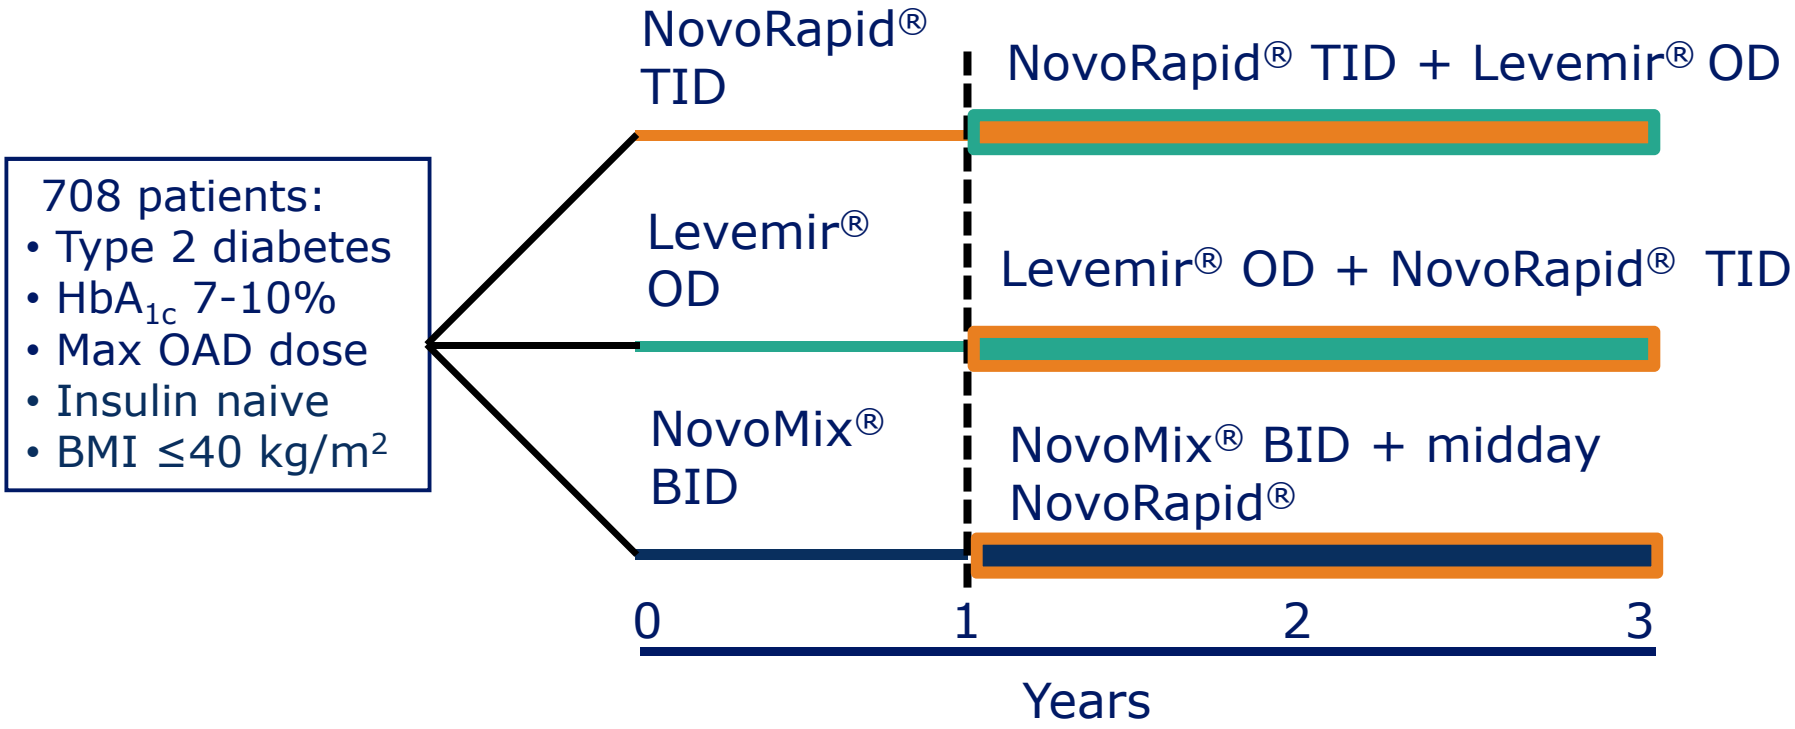
- Lack of evidence based consensus for insulin **initiation** and **intensification** in patients with type 2 diabetes
- Clinically relevant protocol developed that is applicable in the primary care setting

- An independent and academic 3-year, multicentre, open-label, randomised, controlled clinical trial
- Conducted in the United Kingdom and Ireland
- Supported by Novo Nordisk and Diabetes UK

A1chieve®
Together, we can

novo nordisk®

Study design to investigate insulin initiation and intensification



SU therapy replaced by second insulin in the first year if:

- HbA_{1c} ≥10% or
- HbA_{1c} ≥8% on two consecutive occasions

Or if:

- HbA_{1c} >6.5% at end of year one

A1chieve® Together, we can

novo nordisk®

Adapted from Holman *et al. NEJM* 2009; 361:1736-47

Titrate to targets

Blood glucose targets

- Fasting and pre-meal: 4.0-5.5 mmol/l (72-99 mg/dl)
- Two-hours post meal: 5.0-7.0 mmol/l (90-126 mg/dl)

- The 4-T Online Trial Management System suggested dose adjustments using a common algorithm for all groups
- Investigators encouraged to amend suggested doses on clinical grounds and in consultation with patients
- Patients encouraged to modify doses between visits

Outcomes

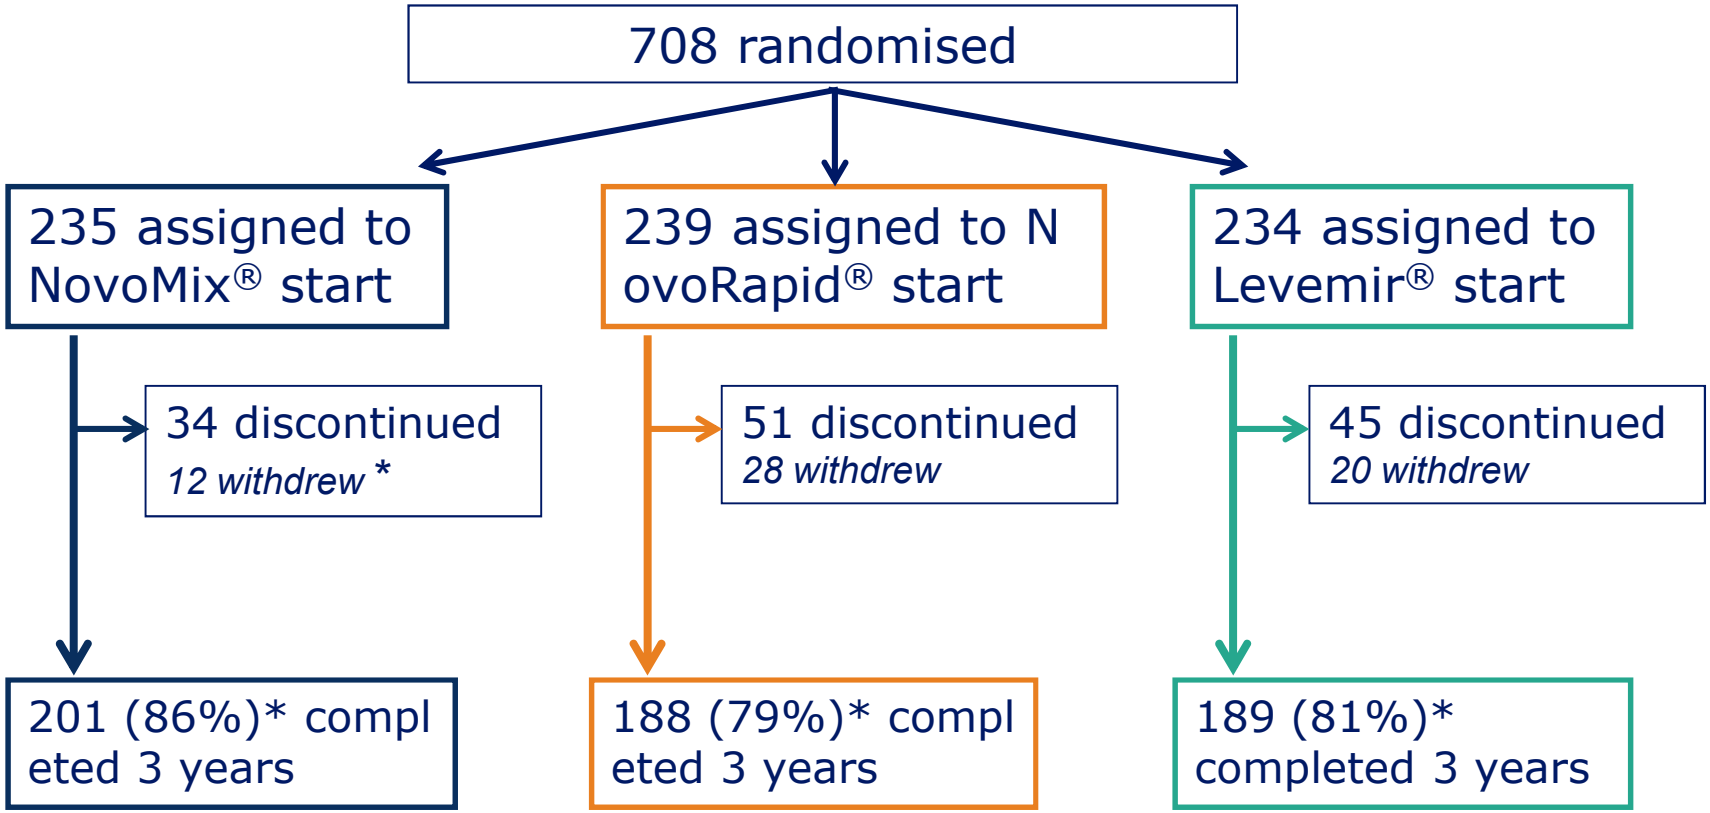
Primary outcome

- HbA_{1c} at 1 years and 3 years

Secondary HbA_{1c} outcomes

- Patients achieving HbA_{1c} ≤6.5%
- Patients achieving HbA_{1c} ≤ 6.5% without minor/major hypoglycaemia
- Weight gain

High patient retention for all insulin analogue study arms



Overall, 82% patients completed the study
*Difference between groups for number of withdrawals, p=0.04

4T: summary (1)

In the first year:

- Addition of a single analogue insulin formulation to metformin and sulfonylurea lowered HbA_{1c} by 0.8 to 1.4%
- Regimens using biphasic or prandial insulin reduced HbA_{1c} to a greater extent than basal, but were associated with greater risks of hypoglycemia and more weight gain

4T: summary (2)

After 3 years:

- Roughly three-quarters of patients had added a second insulin
  - Percentage of patients achieving HbA_{1c} ≤7.0%
    - Levemir® start: 63.2%
    - NovoMix® 30 start: 49.4%
    - NovoRapid® start: 67.4%

4T: summary (3)

After 3 years:

- Median rates of hypoglycaemia (per pt/year)
  - Levemir® start: 1.7
  - NovoMix® 30 start: 3.0
  - NovoRapid® start: 5.7
  - Hypoglycaemia rates were not significantly affected by the achievement of tight control (≤6.5% HbA_{1c})
- Mean weight gain
  - Levemir® start: 3.6 kg
  - NovoMix® 30 start: 5.7 kg
  - NovoRapid® start: 6.4 kg

A1chieve® Together, we can

novo nordisk®

4T Conclusions

- A tight level of control was achieved and maintained over 3 years with Novo Nordisk insulin analogues.
- The overall rate of hypoglycaemia was low and no greater in patients reaching the 6.5% target.
- Due to the progressive nature of type 2 diabetes, insulin dose optimisation and intensification is required over time to maintain glycaemic control.

Home P at al, Diabetes Res Clin Pract. 94:352-63, 2011

ABSTRACT

Aim: The aim of A_1chieve was to remedy the deficit of data on the efficacy and safety of insulin analogues in routine clinical care in less well-resourced/newly developed countries.

Methods: A non-interventional, 6-month, observational study of 66,726 people with type 2 diabetes, both insulin users and non-insulin users, started on insulin detemir, insulin aspart or biphasic insulin aspart in 28 countries across four continents.

Results: Baseline HbA_{1c} (±SD) was poor: 9.5 ± 1.8%. At 6 months, improvement was −2.1 ± 1.7% in the entire cohort, and −2.2 ± 1.7% and −1.8 ± 1.7% for prior non-insulin users and insulin users. All three analogue therapies gave similar results, again independently of prior insulin use, but also from seven pre-specified country groupings. Overall, hypoglycaemia did not increase in those new to insulin, and fell in those switching insulins. There was no change in body weight (−0.1 ± 3.7 kg), while lipid profile and systolic blood pressure (−6.3 ± 17.1 mmHg) were improved.

Conclusions: Beginning insulin analogue therapy in people with type 2 diabetes and poor blood glucose control is associated with marked improvements in diverse aspects of vascular risk factor profile without evidence of clinically significant safety or tolerability problems.

ABSTRACT

Aims: To determine the effects on quality of life after starting insulin with, or switching to, insulin analogue therapies in the 24-week, prospective, non-interventional, observational A_1chieve study conducted across four continents in people with type 2 diabetes.

Methods: Health-related quality of life (HRQoL) was assessed at baseline and at 24 weeks by the validated EQ-5D questionnaire (visual analogue score [VAS] and five dimensions) in 66,726 people who had started using basal insulin detemir, mealtime insulin aspart (with or without a basal insulin) or biphasic insulin aspart 30.

Results: For the overall cohort, reported HRQoL increased significantly by 13.8 points from 63.4 points at baseline to 77.2 points at 24 weeks ($p < 0.001$) (scale 1–100, 100 = best health imaginable). Beginning or changing insulin was associated with a significant increase in HRQoL score (+15.0 points and +11.1 points, respectively), resulting in a similar score at 24 weeks in the two populations (77.8 and 75.9 points). Reported HRQoL also increased statistically significantly in people administering any insulin analogue regimen and across all regions, although there were some marked regional differences in reported HRQoL at baseline.

Conclusion: Compared with baseline scores, beginning insulin with, or switching to, insulin analogue therapies are associated with increased HRQoL.

Summary

- All insulin therapies used during the study scored highly in terms of self-rated health (EQ5D) after week 24
  - Levemir, NovoMix, NovoRapid and Basal + NovoRapid received similar ratings amongst insulin naïve patients and insulin users

Agenda

- Study Design
- Korea Final Result Review
- Overall Summary and Q&A session

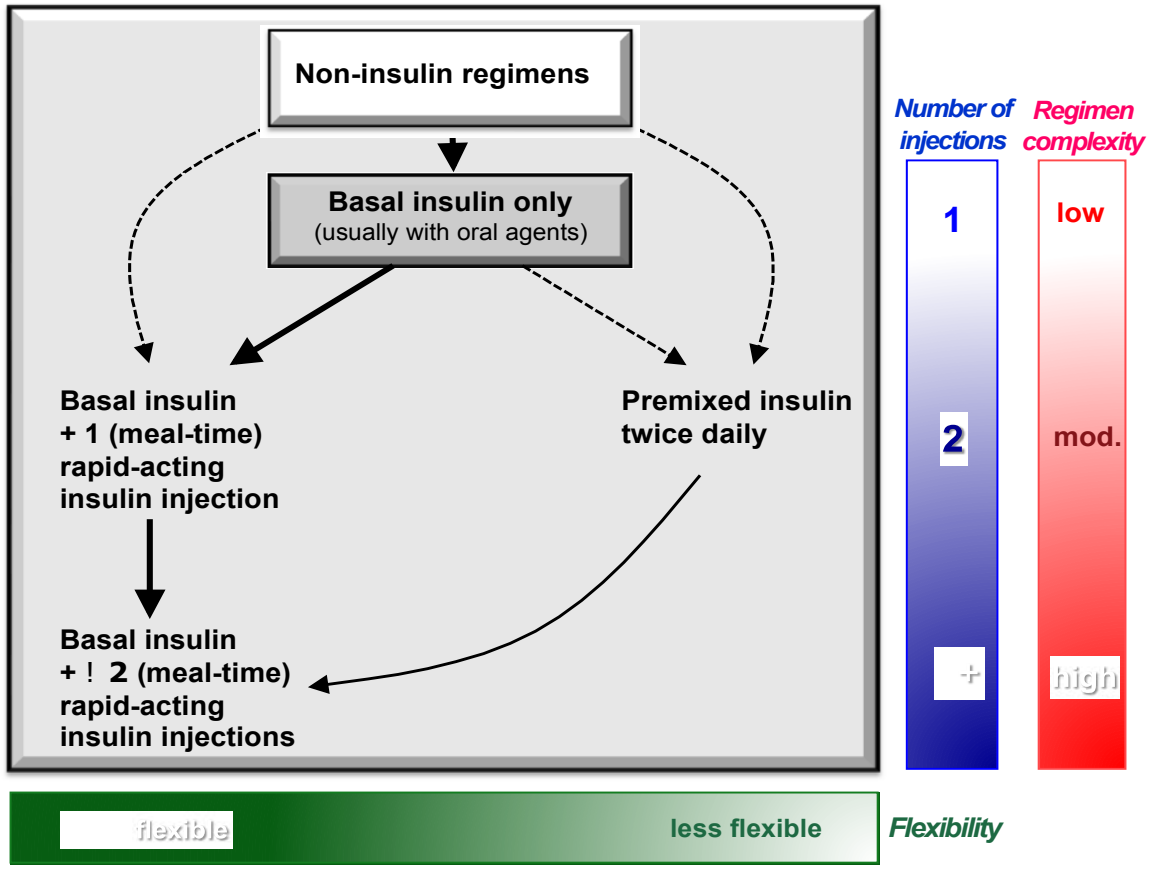
A1chieve
Together, we can

novo nordisk®

Overall summary

- Significant HbA_{1c} reductions on all study insulins
    - 22.7% of Korean patients achieved HbA_{1c} <7.0%
- Low rates of hypoglycaemia on all study insulins with minimal weight gain observed in all treatment groups
- Self-rated health was greater across all study insulins after 24 weeks of treatment

Sequential Insulin Strategies in T2DM



Inzucchi F et al., Diabetes Care, Diabetologia. 19 April 2012 [Epub ahead of print]

Key Messages on Insulin in Type 2 Diabetes (Position Statement of the ADA and EASD)

- Any insulin will lower glucose and HbA1c
- All insulins are associated with some weight gain and some risk of hypoglycemia
- The larger the doses and the more aggressive the titration, the lower the HbA1c, but often with a greater likelihood of adverse effects
- Generally, long-acting insulin analogs reduce the incidence of overnight hypoglycemia, and rapid-acting insulin analogs reduce postprandial glucose excursions as compared with corresponding human insulins (NPH, Regular), but they generally do not result in clinically significantly lower HbA1c

Inzucchi SR et al., Diabetes Care 2012, published online April 19, 2012

Insulin regimen choice should be an individualised approach based on many factors including lifestyle, social, economic, desired glycaemic targets, age, duration of diabetes, co-morbidity and hypoglycaemia risk

Shah S at al, Diabetes Res Clin Pract. 94:364-70, 2011

- Having T2DM has a negative impact on quality of life (QoL).
- Having to deal with lifestyle change, complex treatment regimens, potentially having to manage self-injection, and sometimes fear of hypoglycemia and weight gain can contribute to poor QoL and adverse perceptions of diabetes therapies.
- Consequently, people with T2DM and their physicians often delay starting or optimizing insulin therapy, despite the current burdens of poor glycemic control [4–7].
- Alongside effective glycaemic control, maintaining or improving QoL is an integral part of the successful management of diabetes. Indeed, it is known that measured QoL improves with better glycemic control.

EQ5D: Self-rated health rating scale

1. Mobility
2. Self-care
3. Usual activities
4. Pain / discomfort
5. Anxiety / depression

1. No problem
2. Moderate problem
3. Extreme problem

5-digit code e.g.
12221

This code relates to a 'utility' value between 0 and 1

The EQ VAS records the respondent's self-rated health on a vertical scale

Key deciding factors

- Metabolic parameters – initial glucose levels, osmotic symptoms, glucose profile
- Individual preference – number of injections
- Lifestyle – variable versus predictable
- Occupation
- Presence of physical or cognitive disability
- Social circumstances – living alone, leisure activities, etc.
- Willingness to frequent self monitor
- Insurance coverage and cost
- Compliance

Noncompliance independent associated with increased all-cause mortality in patients with type 2 diabetes

Data were extracted from U.K. general practice records and included patients (*N* = 15,984) with type 2 diabetes

1. **C**linic nonattenders were more likely to be smokers, younger, have higher HbA_{1c}, and have more prior primary care contacts and greater morbidity ($P < 0.001$).

2. Medication noncompliers were more likely to be women ($P = 0.001$), smokers ($P = 0.014$), and have higher HbA_{1c}, more prior primary care contacts, and greater morbidity (all $P < 0.001$)

3. After adjustment for confounding factors:

   A. Medication noncompliance (HR 1.579 [95% CI 1.167–2.135])
   B. Clinic nonattendance of:
      I. 1 or 2 missed appointments (HR 1.163 [1.042–1.299])
